## Paths

- **Path of length  $n$**  in an undirected graph  $G(V, E)$  from vertex  $u$  to vertex  $v$  is an alternating sequence  $u = v_0 e_1 v_1 e_2 v_2 \dots v_{n-1} e_n v_n = v$  of  $n + 1 \in \mathbb{Z}$  vertices  $v_i \in V, i \in \mathbb{N}$  and  $n$  edges  $e_i \in E$  such that the endpoints of edge  $e_i$  are  $\{v_{i-1}, v_i\}$

- When  $G$  is simple, can simply list the vertices

Is *abedab* a path?

Is *deca* a path?

- Path **passes through** its vertices and **traverses** its edges

- **Simple path** does not include the same edge more than once

*abedab* is not simple

- **Circuit** = path that begins and ends at the same vertex, that is,  $u = v$

*bcfeb*

*febcfebcf*

- **Simple circuit** = circuit in which the only repeated vertex is  $v_0 = v_n$

*bcfeb*

*a(ab)b(bc)c*  
length?

*abc*

## Applications

- **6 degrees of separation** = some social scientists estimate the length of the shortest path in an acquaintance graph between you and anyone in the world is about 6
- **Erdős number** = length of shortest path between mathematician Paul Erdős and yourself in a collaboration graph whose edges denote "collaborated on a long paper"
- **Bacon number** = length of shortest path between actor Kevin Bacon and another actor in a collaboration graph whose edges denote "acted in the same movie"

Madonna has a Bacon number of 2.

## Connectivity in $G(V, E)$

- **Vertices**  $v, w \in V$  are **connected** iff there is a path from  $v$  to  $w$  in  $G$

- Recall that edges may cross in a drawing of a graph without going through a vertex
- **Graph**  $G$  is **connected** iff there is a path between every pair of vertices in  $V$ , otherwise it is **disconnected**

## Proof by cases skeleton

**Theorem:** If  $A_1$  or  $A_2$  or ... or  $A_n$  then  $C$ .

**Proof:**

**Let/Assume/Suppose:** Name variables and state what they stand for  
 be general: **any**                      **state any assumptions**

**We must show that  $C$  is true in each of the following cases:**

**Case 1:** If  $A_1$  then  $C$ .

**Case 2:** If  $A_2$  then  $C$ .

...

**Case  $n$ :** If  $A_n$  then  $C$

Thus  $C$  is **true regardless of which is the case.**

**QED**

Clarify your logic with a reason for every assertion  
 Display equations and inequalities clearly

## Circuits and connectivity

**Lemma:** If  $v, w$  are part of a circuit in  $G$  and one edge is removed from the circuit, there still exists a path from  $v$  to  $w$  in  $G$ .

**Proof:** Let  $G$  be a graph with vertices  $V$  and edges  $E$ , and let  $v, w$  be vertices on some circuit  $v_0 e_1 v_1 e_2 v_2 \dots v_{n-1} e_n v_0$  in  $G$  where  $v = v_i$  and  $w = v_j$ . Consider the removal of of some edge  $(v_k, v_{k+1})$ .

**We must show that there is still a path between  $v$  and  $w$ .**

There are 2 cases: the edge was on the path from  $v$  to  $w$  or it was not.

**Case 1:** The edge  $(v_k, v_{k+1})$  was on the path from  $v$  to  $w$ . Let  $v'$  be the vertex on the circuit immediately before  $v$ , and let  $w'$  be the vertex on the circuit immediately after  $w$ . Then  $ww' \dots v_{n-1} e_n v_0 e_1 v_1 e_2 v_2 \dots v'v$  is still a path from  $w$  to  $v$ , and its reverse is a path from  $v$  to  $w$ .

**Case 2:** The edge was not on the path from  $v$  to  $w$ .

Then the path from  $v$  to  $w$  was preserved.

Thus there is still a path from  $v$  to  $w$  **regardless of which is the case.**

**QED**

## Connected components

Graph  $H = (W, F)$  is a **connected component** of graph  $G = (V, E)$  iff  $H$  is a **subgraph** of  $G$ ,  $H$  is **connected**, and no other connected subgraph  $J(X, Y)$  of  $G$  has  $H$  as a subgraph. ( $H$  is a **maximal** connected component.)

A call graph for 1 day of AT&T calls had 53,767,087 vertices (telephone numbers) and > 170 million edges (calls).

Analysis found >3.7 million connected components, about 75% of which were restricted to calls between 2 numbers that only called each other.

There was also 1 large connected component with 44,989,297 telephone numbers (about 80% of all numbers), where every vertex had a path to any other vertex of length  $\leq 20$ .

10/25

10

## Traverse every edge exactly once

The river Pregel runs through Königsburg (now Kaliningrad, Russia) and 7 bridges cross it at various points. In 1736, the mathematician Leonhard Euler often strolled there after Sunday dinner and began to wonder if it was possible to walk from home and back again while crossing each bridge exactly once.

Is there a circuit in this multigraph that contains every edge?

Fall 2023

CSCI 150

11/29

11

## Things Eulerian

- **Eulerian** (aka **Euler**) **circuit** (aka **cycle**, **tour**) for a graph  $G(V, E)$  is a **circuit** that contains **at least 1 edge**, contains **every vertex at least once** and contains **every edge exactly once**
- **Eulerian graph** is a graph that contains an Eulerian circuit
- **Note**:  $G$  may be a directed or an undirected graph
- If a graph  $G = (V, E)$  has an Eulerian circuit, then all vertices in  $V$  have positive even degree.
- If a graph  $G = (V, E)$  is connected and the degree of every vertex of  $G$  is a positive even integer, then  $G$  has an Eulerian circuit.

Thus

**Theorem**: A graph  $G$  has an Eulerian circuit **iff**  $G$  is connected and all its vertices have positive even degree.

- **Eulerian** (aka **Euler**) **path** for a graph  $G(V, E)$  is a **path** that contains **at least 1 edge**, contains **every vertex at least once** and contains **every edge exactly once**

See your text for proofs of this material

## Is a graph Eulerian?

**Just proved:** If a graph  $G = (V, E)$  has an Euler circuit, then all vertices in  $V$  have positive even degree.

So the **contrapositive must also be true:**

**Theorem:** If any vertex in  $G = (V, E)$  has odd degree, then the graph does not have an Eulerian circuit.

**Corollary:** In a connected graph  $G = (V, E)$  there is an Euler path but not an Euler circuit iff there are exactly 2 vertices of odd degree.

Is there a circuit in this multigraph that contains every edge?

Nope. Sorry, Euler.

The Königsburg bridge graph is not Eulerian.  
And it doesn't even contain an Eulerian path.

CSCI 150

13/25

13

## How to build an Euler circuit

Find a circuit  $C$  in  $G$

$G$ :

Remove all edges of  $C$  from  $G$  and all vertices that are then isolated to form a subgraph  $G'$

Find a circuit  $C'$  in  $G'$

Patch  $C$  and  $C'$  together to form  $C''$   
Drop  $C''$  from  $G$  and repeat while  $V \neq \emptyset$

$G$ :

## Applications of Eulerian circuits

- Travel through a town so that every block is traversed exactly once.
    - pick up garbage**
    - deliver mail**
    - build a power line**
  - How to do that?
  - Find an Euler circuit if you have to return where you started
  - Otherwise, find an Euler path
  - Circuit layout
  - Network multicasting
  - DNA sequencing in molecular biology
  - Design a tour from  $A$  to  $B$  through this museum that passes through each door exactly once
- 
- 
- Any question

## Pass through every vertex exactly once

A **dodecahedron** is a 12-sided solid with pentagonal faces.

In 1859 the Irish mathematician Sir William Hamilton designed a puzzle that labeled each face with a city

Paris London New York

and asked for a trip that would visit each city exactly once and return to the starting point.

Here's a "flattened" version of the dodecahedron where each vertex represents a corner and a solution to the puzzle.

Fall 2023

CSCI 150

17/25

17

## Things Hamiltonian

- **Hamiltonian path in graph**  $G(V, E)$  = simple path that passes through every vertex exactly once
- **Hamiltonian circuit in graph**  $G(V, E)$  = simple circuit that passes through every vertex exactly once
- In general, the existence and detection of Hamiltonian paths and circuits graphs are **NP-complete problems** (no polynomial-time algorithm is likely to exist for them)
- But there are some sufficient conditions
  - If  $G$  is a simple graph with  $|V| \geq 3$  vertices all of degree  $\geq |V|/2$  then  $G$  has a Hamiltonian circuit
  - If  $G$  is a simple graph with  $|V| \geq 3$  vertices and the degree sum of any two non-adjacent vertices is  $\geq |V|$  then  $G$  has a Hamiltonian circuit

Fall 2023

CSCI 150

18/25

18

## More Hamiltonian results

- If there is a vertex of degree 1, there are no Hamiltonian paths or circuits
- If there is a vertex of degree 2, then both edges incident with it must be part of any Hamiltonian path or circuit
- A graph  $G(V, E)$  with a Hamiltonian circuit has a connected subgraph  $H(W, F)$  such that:
  - $W = V$
  - $|W| = |F|$
  - Every vertex of  $H$  has degree 2

Fall 2023

CSCI 150

19/25

19

## Planarity

A graph is **planar** iff it can be drawn on the plane with no edges that cross one another

Not planar

Applications to the design of  
electronic circuits and road networks

Fall 2023

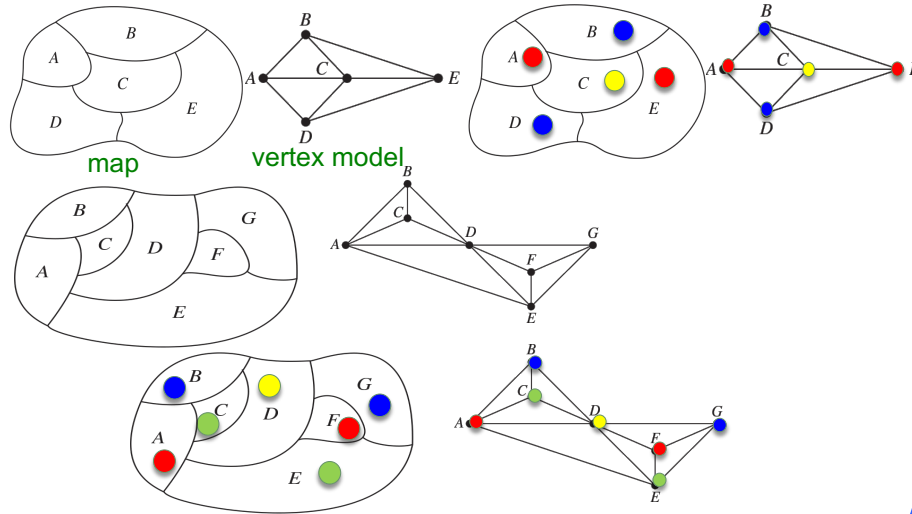

CSCI 150

20/25

20

## Graph coloring

A **coloring** of a graph assigns a color to each vertex so that no two adjacent vertices are assigned the same color

Fall 2023

CSCI 150

21/25

21

## Chromatic number

The **chromatic number** of a graph = the least number of colors necessary to color it

What is the chromatic number of  $K_n$ ?

What is the chromatic number of  $K_{m,n}$ ?

Fall 2023

CSCI 150

22/25

22

## The 4-color theorem

**Theorem:** The chromatic number of a planar graph is no more than 4.  
Conjectured by Augustus Guthrie in 1852.

Temporarily "proved" by Alfred Kempe in 1879 until an error was found in the proof in 1890

Proved by Kenneth Appel and Wolfgang Halen in 1976 with a computer that examined 1834 classes of counterexamples and proved that none of them could exist, but errors were found after publication. These were corrected in their 1989 book

Subsequent proofs have reduced the number of counterexample classes to 633 but all of them use a computer

Highly recommended if graph coloring intrigues you:

## Proof methods (so far)

- Truth table
- Sequence of statements with reasons
- Valid argument forms (modus ponens, modus tollens,...)
- Predicate logic (quantification, existence, uniqueness)
- Proof by cases
- Generalization from the generic particular
- Proof by contradiction
- Proof by contraposition
- Mathematical induction
- Strong mathematical induction
- Algebraic proof by set theory
- Algebraic proof by properties of functions
- Algebraic proof by combinatorics
- Algebraic proof by graph theory
- Exhaustive proof by computer
